Bachelor’s or Master’s Thesis: 
Development of a Dedicated Small Animal PET

In Positron Emission Tomography (PET) imaging (Fig. 1), a patient or animal is injected with a radioactive substance emitting positrons during decay. The positron annihilates with an electron from the subject’s body, thus producing two photons which propagate through the body in opposite directions. These photons are detected outside the body using a ring of PET detectors. These PET detectors are typically scintillators, converting the 511 keV gamma photon to a high number of optical photons which are detected by underlying photosensitive detectors.

In biomedical and preclinical studies, the mouse model is widely used. PET enables to detect and quantify radiopharmaceuticals \textit{in vivo} at molecular level. Thus, PET became well-established in preclinical pharmacology, genetics as well as pathology.

The goal is to develop and characterize a small-animal PET scanner based on a read-out architecture developed in this group (successor of [2]). The scanner architecture shall allow the study of different detector concepts such as segmented and monolithic scintillators and novel calibration procedures.

This thesis may include

- construction of the scanner mechanics and cooling
- simulation study of possible geometries and designs
- commissioning of the scanner and detectors
- study and characterization of suitable detector geometries
- calibration of the developed system
- characterization and optimization of the scanner
- image reconstruction

Possible candidates may choose their special field of interest. If desired, the topic allows a collaboration between a group of students focussing on different aspects of the topic.
